

## TDA 5660 P Modulator for TV, Video and Sound Signals

The monolithically integrated circuit TDA 5660 P is especially suitable as modulator for the 48 to 860 MHz frequency range and is applied e.g. in video recorders, cable converters, TV converter installations, demodulators, video generators, video security systems, amateur TV applications, as well as personal computers.

- Synchronizing level-clamping circuit
- Peak white value gain control
- Continuous adjustment of modulation index for positive and negative modulation
- Dynamic residual carrier setting
- FM sound modulator
- AM sound modulator
- Picture carrier to sound carrier adjustment
- Symmetrical mixer output
- Symmetrical oscillator with own RF ground
- Low radiation
- Superior frequency stability of main oscillator
- Superior frequency stability of sound oscillator
- Internal reference voltage

### Circuit description

Via pin 1, the sound signal is capacitively coupled to the AF input for the FM modulation of the oscillator. An external circuitry sets the preemphasis. This signal is forwarded to a mixer which is influenced by the AM modulation input of pin 16. The picture to sound carrier ratio can be changed by connecting an external voltage to pin 16, which deviates from the internal reference voltage. In case, the sound carrier should not be FM but AM modulated, pin 1 should be connected to pin 2, while the AF signal is capacitively coupled to pin 16. Through an additional external dc voltage at pin 16, the set AM modulation index can be changed by overriding the internally adjusted control voltage for a fixed AM modulation index. At the output of the above described mixer the FM and/or AM modulated sound signal is added to the video signal and mixed with the oscillator signal in the RF mixer. A parallel resonant circuit is connected to the sound carrier oscillator at pin 17, 18. The unloaded  $Q$  of the resonant circuit must be  $Q = 25$  and the parallel resistor  $R_T = 6.8 \text{ k}\Omega$  to ensure a picture to sound carrier ratio of 12.5 dB. At the same time, the capacitive and/or inductive reactance for the resonance frequency should have a value of  $X_C \approx X_L \approx 800 \Omega$ .

The video signal with the negative synchronous level is capacitively connected to pin 10. The internal clamping circuit is referenced to the synchronizing level. Should the video signal change by 6 dB, this change will be compensated by the resonant circuit which is set to the peak white value. At pin 11, the current pulses of the peak white detector are filtered through the capacitor which also determines the control time constant. When pin 12 is connected to ground, the RF carrier switches from negative to positive video modulation.

With the variable resistor of  $R = \infty \dots 0 \Omega$  at pin 12, the modulation depth, beginning with  $R = \infty$  and a negative modulation of  $m_{D/N} = 80\%$ , can be increased to  $m_{D/N} = 100\%$  and continued with a positive modulation of  $m_{D/P} = 100\%$  down to  $m_{D/P} = 88\%$  with  $R = 0 \Omega$ . The internal reference voltage has to be capacitively blocked at pin 2.

The amplifier of the RF oscillator is available at pins 3-7. The oscillator operates as a symmetrical ECO circuit. The capacitive reactance for the resonance frequency should be  $X_C \approx 70 \Omega$  between pins 3, 4 and 6, 7 and  $X_C \approx 26 \Omega$  between pins 4, 6. In order to set the required residual carrier suppression, pin 9 is used to compensate for any dynamic asymmetry of the RF mixer during high frequencies of  $> 300$  MHz. The oscillator chip ground, pin 5, should be connected to ground at the oscillator resonant circuit shielding. Via pin 3 and 7 an external oscillator signal can be injected inductively or capacitively. The peripheral layout of the pc board should be provided with a minimum shielding attenuation of approx. 80 dB between the oscillator pins 3-7 and the modulator outputs 13-15.

For optimum residual carrier suppression, the symmetric mixer outputs at pins 13, 15 should be connected to a matched balanced-to-unbalanced broadband transformer with excellent phase precision at 0 and 180 degrees, e.g. a Guanella transformer. The transmission loss should be less than 3 dB. In addition, an LC low pass filter combination is required at the output. The cut-off frequency of the low pass filter combination must exceed the maximum operating frequency.

If the application circuit according to figure 1, 2 is used, a multiplication factor  $V/RF$  (application) =  $V/RF$  (data sheet) 3.9 must be used to convert a  $300 \Omega$  symmetrical impedance to an asymmetrical impedance of  $75 \Omega$  for the stated RF output voltage  $V_a$  of the type specification in order to ensure a transmission attenuation of 0 dB for the balanced-to-unbalanced mixer.

**Maximum ratings**

		min	max		Remarks
Supply voltage	$V_S$	-0.3	14.5	V

### Description of the measurement configuration to measure the noise voltage, video in sound

Figure 8

**Calibration:** A signal of  $V_{AF\ rms} = 270\text{ mV}$  and  $f = 0.4\text{ kHz}$ , corresponding to a nominal deviation of 30 kHz, is connected to the sound input, and the demodulated AF reference level at the audio measurement device is defined as 0 dB. No video signal is pending.

**Measurement:** 1) The AF signal is switched off and the FuBK video signal is connected to the video input with  $V_{VIDEO\ pp} = 1\text{ V}$ . The audio level in relation to the reference calibration level is measured as ratio  $a_{p/s} = 20\text{ log}(V_{FUBK})/(V_{nominal})$ .  
2) AF and video signal are switched off. The noise ratio in relation to the AF reference calibration level is measured as signal-to-noise ratio  $a_{S/N}$ .

**Calibration:** AF signals are switched off; video signal is pending at the video input; device to measure modulation set at AM is adjusted to video carrier; filter: 300 Hz...200 kHz; detector  $(P+P)/2$ ; resulting modulation index is defined as  $m_V = 0$  dB.

- Measurement:**
- 1) Measurement of interference product ratio sound in video during FM modulation of the sound carrier: AF signal is connected to FM sound input; video signal is switched off; device to measure modulation is set to AM; filter: 300 Hz... 3 kHz; detector:  $(P+P)/2$ ; a ratio of  $a_{S/P} = 20 \log m_{V/S}/m_V$  is derived from the resulting modulation index  $m_{V/S}$ .
  - 2) Measurement of interference product ratio sound in video during AM modulation of sound carrier: AF signal is connected to AM sound input; otherwise identical with measurement 1.
  - 3) Measurement of signal-to-noise ratio in video without AM/FM modulation of sound carrier: AF signals are switched off; video signal is switched off; control voltage at pin 11 is clamped to value present during connected video signal; modulation device is set to AM; filter: 300 Hz... 3 kHz; detector: RMS  $\sqrt{2}$ ; readout in dB to reference level of calibration is  $a_{S/P}$ .
